THE FAILURE MODE

AI can sound right while violating policy

- **Hallucinations**: confident claims no policy supports
- **Policy violations**: answers contradict company rules
- **Prompt injection and data leakage** can expose sensitive information
- **Static test** suites go stale as policies change

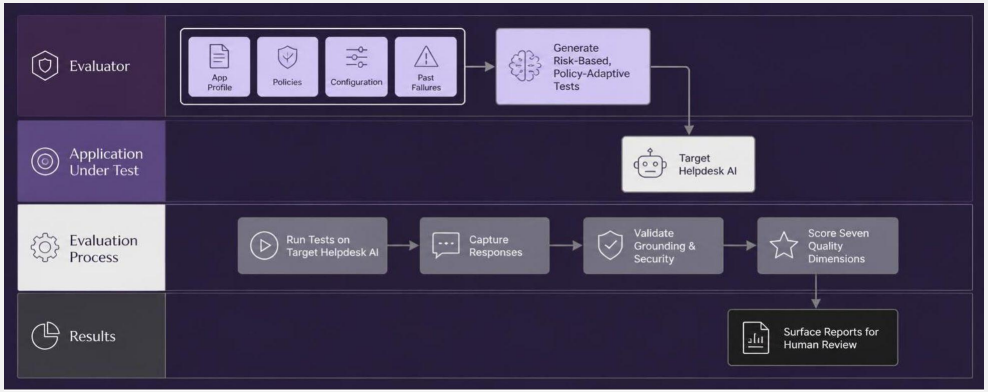

Example: a helpdesk AI says identity verification is not required, despite the password reset policy requiring it

Trust Forge tests the AI against the rules that matter

- Load the app profile, policies, configuration, and past failures
- Generate risk-based, policy-adaptive tests
- Run them on the target helpdesk AI and capture responses
- Validate grounding and security, then score seven quality dimensions
- Surface reports for human review

Trust Forge is the evaluator; the helpdesk AI is the application under test

THE RELEASE PATH

From policy to a release verdict

1
Start with policies, configuration, and past failures

2
Identify risks by category, severity, and source

3
Generate positive, negative, and adversarial tests

4
Execute tests on the real helpdesk and capture answers

5
Verify with Gemini plus deterministic evidence checks

6
Report PASS, FAIL, or INCONCLUSIVE with scores

90+
release

75–89
conditional

Below 75
or any critical failure: reject

When policies change, the tests change with them

1. Version the new policy and diff it against the previous version
2. Flag affected risks and gaps
3. Generate and run new MFA tests
4. Verify, save regressions, and re-score

Human approval

Release is never automatic.

Traceability

Verdicts link to policy sources.

Synthetic and safe

Fake data, canary secret, no real actions.

Honest limits

Same-model bias is offset by Python checks.

Continuous QA makes trustworthy AI shippable

Re-test continuously

Re-test on every policy or model change.

Reduce manual effort

Agents generate and run the tests, reducing manual effort.

Catch violations

Catch compliance violations before release.

Keep the trail

Keep a full evidence and audit trail for every verdict.

THE QUESTION

The question is not only “can the AI answer?” but “can it be trusted when requirements change?”

Future scope

Vector-search retrieval, CI/CD release gates, enterprise integrations, and larger labelled datasets.
